

E3SMv1.1 Biogeochemistry simulation campaign – overview of configuration and historical simulations (JAMES, 2020)

Susannah M. Burrows, Mathew Maltrud, Xiaojuan Yang, Qing Zhu, Nicole Jeffery, Xiaoying Shi, Daniel Ricciuto, Shanlin Wang, Gautam Bisht, Jinyun Tang, Jon Wolfe, Bryce E. Harrop, Balwinder Singh, Lee Brent, Tian Zhou, Philip Cameron-Smith, Nathan Collier, Min Xu, Elizabeth C. Hunke, S. M. Elliott, A. K. Turner, Hongyi Li, Hailong Wang, Jean-Christophe Golaz, Ben Bond-Lamberty, Forrest M. Hoffman, William J. Riley, Peter E. Thornton, Kate Calvin, L. Ruby Leung.

Motivation: There is large uncertainty in future changes in terrestrial and ocean carbon.

- Changes in carbon varied dramatically across models in CMIP5.
- Land models that included nitrogen limitations tended to have weaker terrestrial carbon uptake.
- These results suggest that model structure and nutrient limits matter for prediction of future climate.

Change in Vegetation Carbon

Source: Jones et al. (2013)

Two pathways for carbon cycle- climate feedbacks

Concentration-carbon feedback

Climate-carbon feedback

Progressive nutrient limitation hypothesis:

Nutrient limitations reduce the response of ecosystem growth and carbon uptake to increases in atmospheric CO₂ (Luo et al., 2003)

Simulation Plan

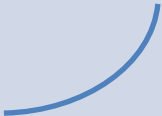

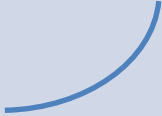

- V1 Science Question: What are the effects of nitrogen and phosphorous on climate-biogeochemistry interactions, and how sensitive are these interactions to model structural uncertainty?

The E3SMv1.1 BGC model configuration

- Terrestrial:
 - Two approaches to soil biogeochemistry (CTC and ECA), both including N and P limits on C uptake
- Ocean/ice:
 - Based on the Biogeochemical Elemental Cycling model (BEC), including N, P, Si, Fe
 - Includes ocean-ice biogeochemical interactions

Simulation plan

	CO ₂ input to radiation (greenhouse effect)	CO ₂ input to carbon cycle (fertilization effects)	Non-CO ₂ climate forcings (LULCC, aerosols...)	Reason
Fully-coupled <i>(BDRD-hist)</i>			historical	Simulates the fully-coupled system
Biogeochemically-coupled <i>(BDRD-hist)</i>			historical	Isolates the carbon-cycle response to CO ₂ (fertilization)
Radiatively-coupled <i>(BCRD-hist)</i>			historical	Isolates carbon-cycle response to climate change
CO ₂ constant <i>(BCRC-hist)</i>			historical	Isolates effect of non-CO ₂ historical forcings
All forcings constant <i>(CNST-forcing)</i>			constant	Control for model drift in absence of forcings

Land biogeochemistry: high-level results

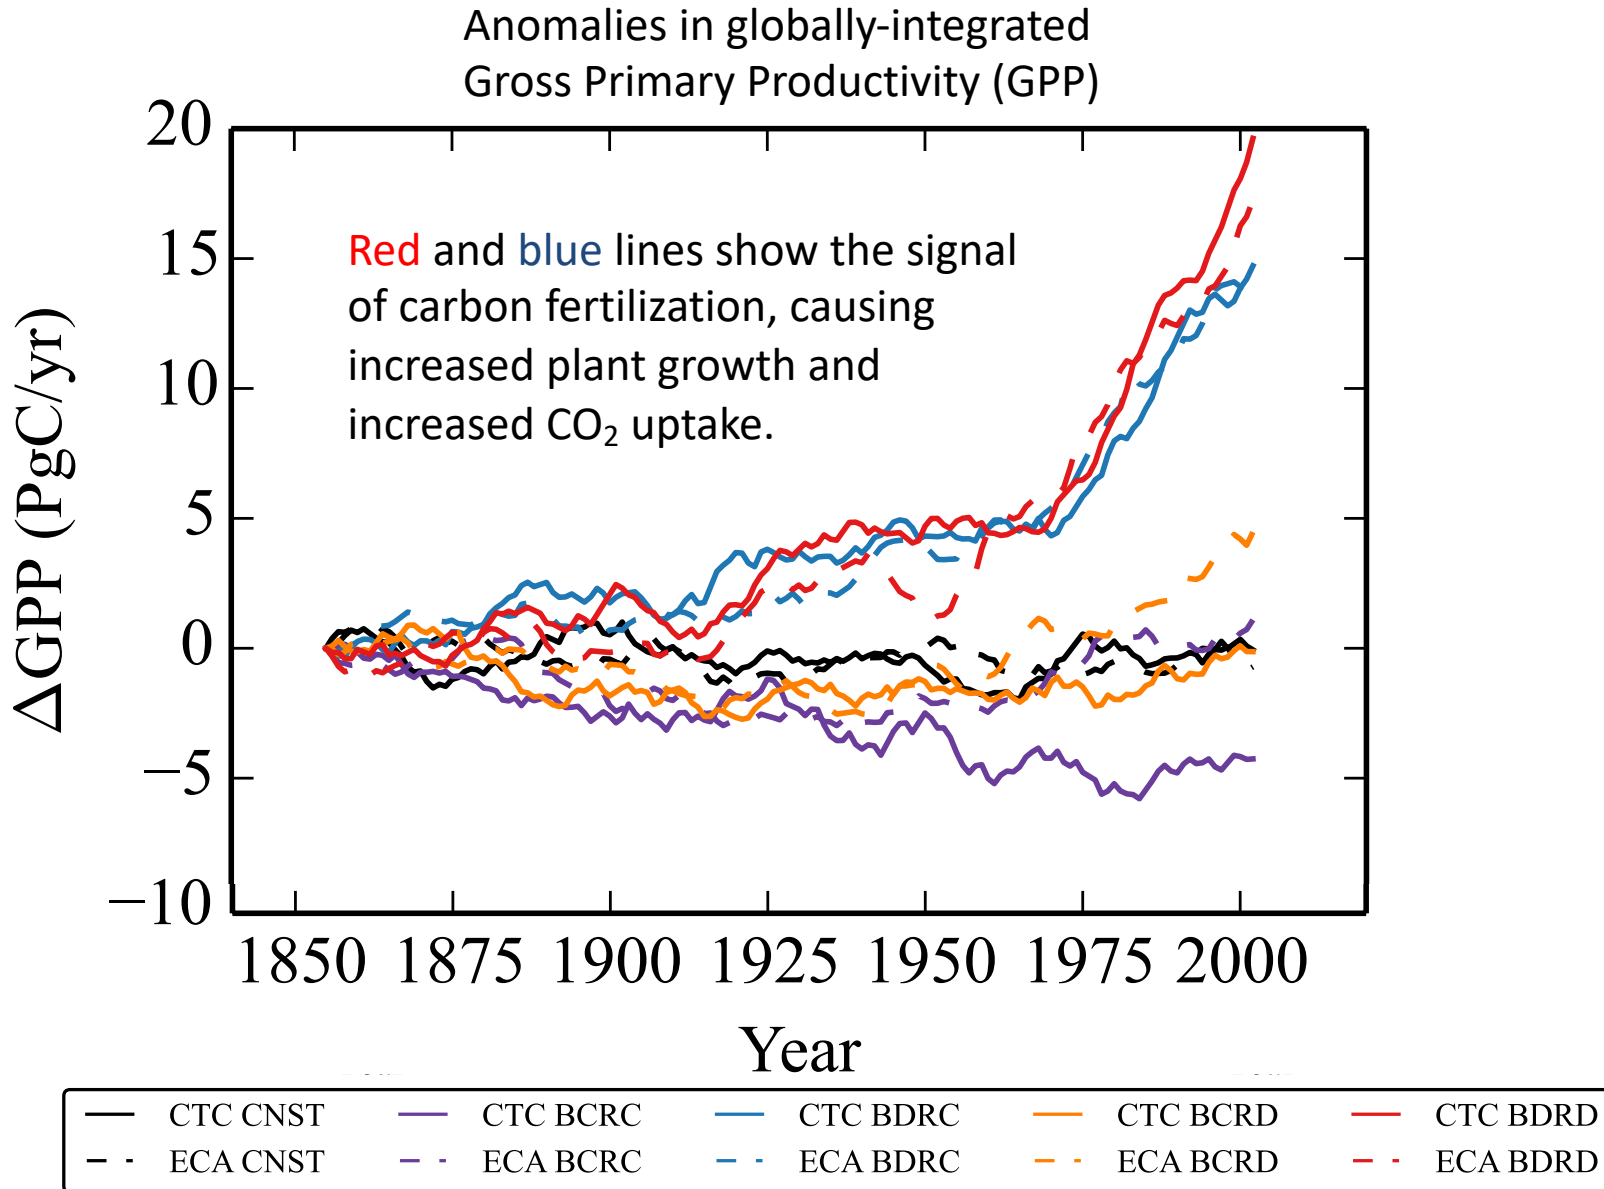

ILAMB global benchmarking for land model

- Overall, both CTC and ECA simulations perform better than most CMIP5 models across a range of metrics.

Response of plant growth (GPP) to carbon fertilization effect is similar in CTC and ECA

Impacts of CO₂ increase on GPP

Constant CO₂
(BCRC-hist)

- GPP is highest in tropical forest ecosystems (as expected)

Total loss of carbon from land since 1850 is comparable to observational estimates in default (CTC) configuration

Change in total land ecosystem carbon (TEC) since 1850

- Purple, orange: Land carbon declines over the 20th century due primarily to deforestation.
- Blue, red: In biogeochemically-coupled simulations, increased plant growth partly compensates.
- Arrows indicate approximate range of observationally-based estimates (Khaliwala et al., 2013).
- Total loss of carbon is much lower in ECA, due to stronger phosphorus limitation.

Ocean / sea ice BGC: high-level results

Net CO₂ flux from ocean to atmosphere (mmol/m²/yr), present-day

MODEL (BDRD-hist, 1977-2006)

OBS (World Ocean Atlas)

- Red colors are fluxes out of ocean (outgassing)
- Blue colors are fluxes into ocean (uptake / sink)

Total ocean carbon uptake since 1850:

- Benchmark: 150 ± 20 PgC/yr (Le Quéré et al., [2018](#))
- E3SMv1.1-BGC: ~ 93 PgC/yr

Ocean surface Chl-a – too little biomass

MODEL (BDRD-hist, 1977-2006)

OBS (SeaWiFS satellite, 1997-2010)

Log(ocean surface Chl-a) (mg/m^3)

Possible sources of bias:

- Lack of parameterized lateral mixing along isopycnal surfaces (Redi mixing).
- Biases in riverine nutrient inputs.
- Ocean mixed-layer depth biases, which lead to too-little overturning of nutrients in regions like the North Atlantic.
- Coastal underprediction is partly a resolution issue.

These issues are being addressed in v2 developments.

Carbon cycle – Climate feedback analysis

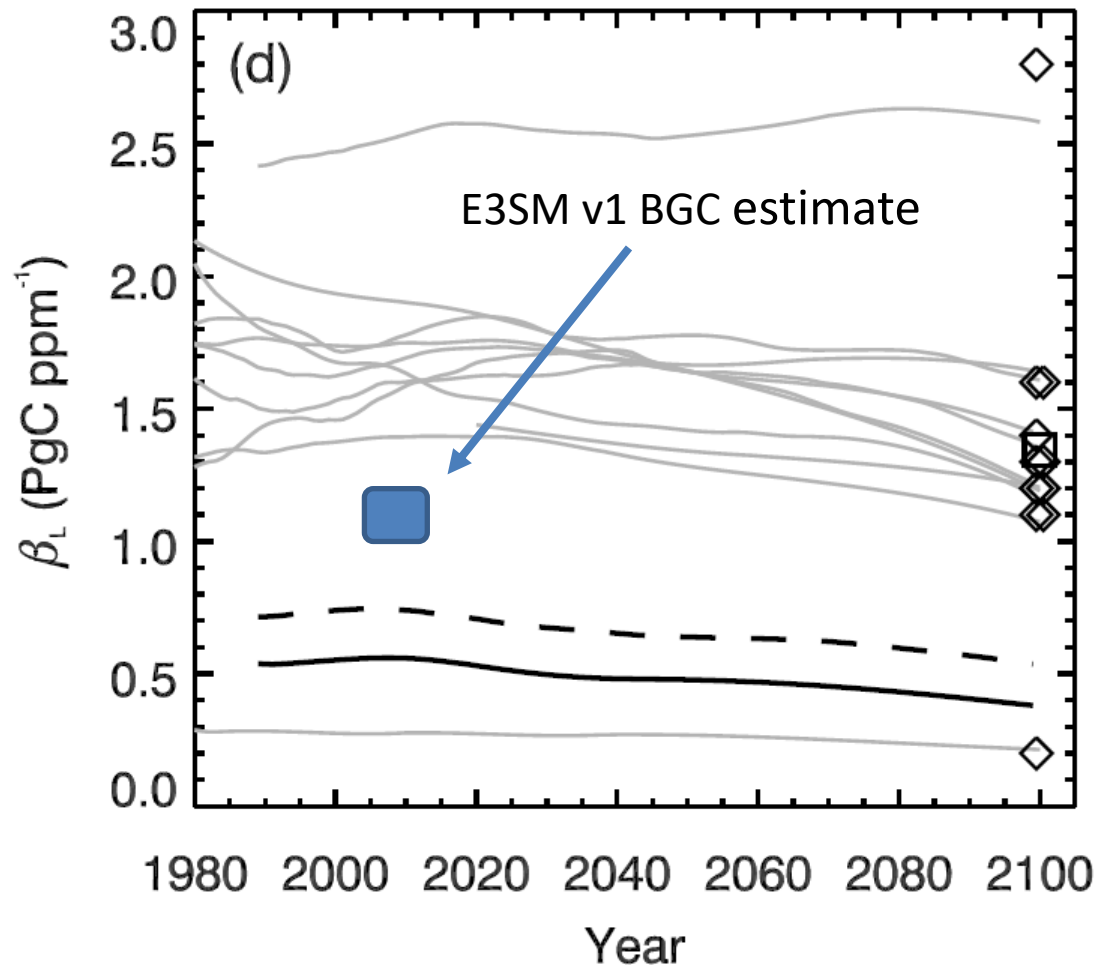

E3SM land CO₂ – climate feedbacks are comparatively weak (~expected)

Beta (Response of CO₂ uptake to CO₂ concentration, PgC/ppmv)

Differences:

- Different physical climate
- Different land model
 - Physics and BGC
- Active P cycle
- E3SM is using dynamic LULCC

Plotted on data from Thornton et al. 2009

E3SM land CO₂ – climate feedbacks are comparatively weak (~expected)

Gamma (Response of CO₂ uptake to temperature, PgC/K)

Differences:

- Different physical climate
- Different land model
 - Physics and BGC
- Active P cycle
- E3SM is using dynamic LULCC

Plotted on data from Thornton et al. 2009

Summary / Outlook

- Conducted E3SMv1.1-BGC historical simulations with two land model configurations.
 - Both perform well on ILAMB land model observational benchmarks
 - Structural differences occur in nutrient limitation and nutrient pools
 - Both configurations have comparatively weak carbon-climate feedbacks, supporting the hypothesis that such feedbacks are weaker in models where nutrient limitations are represented
- Ocean carbon cycle: several sources of bias were identified, which are being addressed for v2.
- Additional papers published / in progress will describe responses to future scenarios, land nutrient limitations and structural uncertainties, sea ice biogeochemistry, and feedbacks on atmospheric dynamics

Thank you!
